Are passive optical networks expensive

Overview

The near-universal adoption of passive optical network (PON) technologies in the fiber-to-the-home market has driven the product pricing from premium “bleeding-edge” down to commodity. With tens of millions of ONTs shipping to the carriers each year, prices continue to fall while. In essence, a PON is a fiber-optic system that delivers data from a single source to multiple endpoints using only unpowered devices for signal distribution, a key differentiator from systems that rely on electronic equipment throughout the network. In practice, PONs are typically used for the last mile between Internet service providers (ISP) and their customers. In this use, a PON. Cost Efficiency: PON's passive design reduces installation and operational costs, making it ideal for budget-conscious projects. Reliability and Security: AON's point-to-point architecture ensures robust security. Passive Optical LAN has clear economic advantages over traditional enterprise networks. The "passive" in its name refers to its use of unpowered optical splitters to divide and direct the signal, which simplifies the network. While passive optical network technology has been around for years, evolving standards, cost efficiencies and AI-driven demand for bandwidth are pushing it further into the mainstream.

A PON takes advantage of wavelength-division multiplexing (WDM), using one wavelength for downstream traffic and another for upstream traffic on a single mode fiber (ITU-T G.652, typically OS2). BPON, EPON, GEPON, and GPON have the same basic wavelength plan and use the 1490 nanometer (nm) wavelength for downstream traffic and 1310 nm wavelength for upstream traffic. 1550 nm is reserved for optional overlay services, typically RF (analog) video.
