Core switch with 100 VLANs

Overview

Enables IP routing between VLANs, subnets, and security zones, with advanced routing protocols. Modular chassis or stackable designs make it easy to scale as your network. A core switch is the backbone of a large-scale network, designed to handle massive volumes of traffic with ultra-low latency and maximum reliability. Sitting at the top of the hierarchical model, core switches interconnect distribution layer switches and provide high-speed data transfer across. This post will deal with creating Layer 2 VLANs on Cisco switches and performing all relevant configurations. By default, only VLAN 1 is configured on the switch, so if you connect hosts on an out-of-the-box switch they all belong to. Should the VLANs be created and configured on the core switch, or directly on the Peplink 3?

Which approach is considered best practice, and why?

Thanks in advance for your advice! Either is fine, but whatever you choose, that needs to be the one and only place you manage them from or add new ones. If you plan to configure many VLANs on the device and to not enable routing, you can set the Switch Database Management (SDM) feature to the Access template, which configures system resources to support the maximum number of unicast MAC addresses. We will be using a M4300-8X8F as the core switch with two M4250-8G2FX-PoE+ switches.

How to Create and Configure VLANs on a Cisco Switch with Example

Best practice is to create VLANs on the core switch. It depends on what the VLAN is for. What is in it, what connects to it (and from where), and how secure it needs to be. Based on that, you
