Can a fiber optic splitter split transceiver signals

Overview

Fiber splitters can effectively split optical signals into several signals of equal proportions and distribute them to different user terminals, thereby realizing the function of multiple users sharing one optical fiber line. Unlike active devices (which require power), splitters operate without electricity, relying solely on the physics of. An optical splitter is a crucial passive fiber optic device that splits and combines optical signals. Conversely, it can also combine multiple signals into one. Its primary role is in Passive Optical Networks (PON), which are the foundation of. A fiber broadband provider typically determines and overall split ratio for the network, such as 1x32 or 1x64, and uses combinations of splitters to meet that ratio with each PON port. 1x32 splits were common in North America for G-PON architectures.
