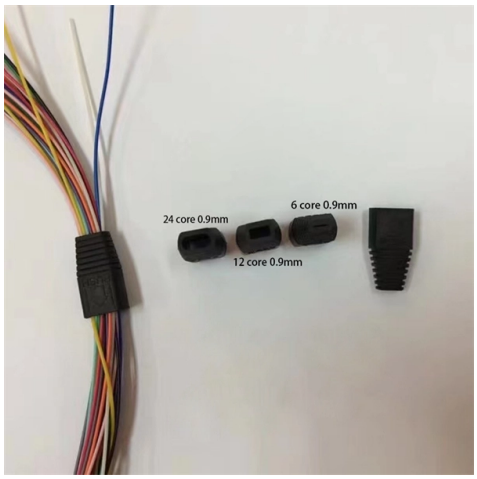
High latency in fiber optic router networking



Overview

To achieve ultra-responsive services, engineers must adopt a holistic strategy: deploying hollow-core fibres to speed up light, reducing regenerator counts, and utilizing direct-attach optical transceivers. Traditional solid-core fibres are limited by the refractive index of glass. Latency in optical networks isn't just a technical metric; it's a physical reality. It arises from the propagation delay of light, optical-to-electrical conversions in repeaters, and signal processing within network devices. Data packets are still being transported at the same bit rate but due to latency they are delayed and affect the. For AI clusters, High-Performance Computing (HPC), and high-frequency trading (HFT), factors like signal propagation, Forward Error Correction (FEC), device hop counts, and excess cable length can become real bottlenecks for interconnect efficiency in low latency networks. While fiber optics are known for their high-speed capabilities, latency still affects how quickly information is transmitted between devices, servers, and users. Even small delays can impact. Network latency can make or break user experience. Gamers feel every millisecond of delay; video conferencing teams struggle when jittery lag ruins every session; business application users watch productivity tank as they wait for slow responses. You've probably spent more time troubleshooting. Is your router plugged directly into the ONT?

Or is there a ISP provided “modem”/router in between your router and the ONT?

Are you DHCP, Static IP, PPPoE?

Can you direct connect 1 computer to the ONT for a while and see if it continues?

Or use the ISP supplied router for a bit?
