Instantaneous overcurrent protection for high-voltage switchgear

Overview

To achieve these safety levels in compact or high-power designs, manufacturers often integrate arc flash relays that use optical fiber or point sensors interlocked with over current to trip the main incoming breaker the moment light from an arc is detected plus over current detection. To achieve these safety levels in compact or high-power designs, manufacturers often integrate arc flash relays that use optical fiber or point sensors interlocked with over current to trip the main incoming breaker the moment light from an arc is detected plus over current detection. Instantaneous Overcurrent Protection (IOCP) is a protection scheme used in power systems to rapidly clear short-circuit faults. Its defining feature is zero intentional time delay (or minimal delay), with typical operating times of 20–50 ms, complying with IEC 60255-151 (Overcurrent Protection. Instantaneous protection helps to protect equipment against phase-to-phase, phase-to-neutral and phase-to-ground short circuits. The protection operates with a definite time characteristic. The protection offers two. Overcurrent protection prevents damage from the overheating of critical components and conductors, further preventing fires and injury. These protection devices, namely relays, can respond instantly to serious problems, or allow for short recovery time following minor, routine events. Perhaps the. There are three fundamental objectives to overcurrent coordination that engineers should keep in mind while selecting and setting protective devices. Life safety requirements are met if protective devices are rated to carry and interrupt maximum available load. Current transformer (CT) saturation can cause reduced operating current to microprocessor-based relays even as fault current increases.
