Network rack air intake and exhaust

Overview

The foundation of data center airflow management is the Hot Aisle-Cold Aisle design, where cabinets are placed in alternating rows, with IT air intakes (cold aisles) and IT air exhausts (hot aisles) each facing one another. This configuration allows data center operators to focus cooling airflow only where it y assumption underlies the hot aisle-cold aisle configuration: that all IT equipment. The port-side intake refers to the front side, or port side, of a switch pulling cool air into the device and expelling hot air out of the power side, or rear of the device. Port-side Intake, power side exhaust is the most commonly occurring switch configuration. With Nexus switch. Sealing the open gaps in server racks is a well-known best practice when implementing airflow management improvements in a data center.
