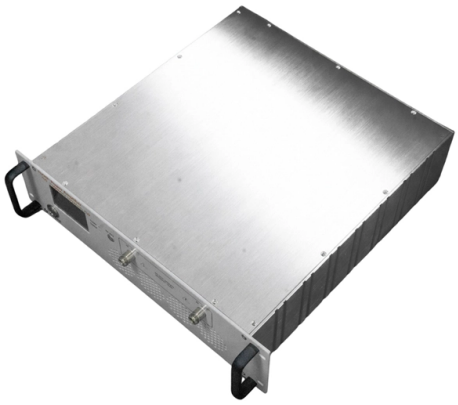
Relay protection start-up and tripping



Overview

Learn recommended troubleshooting steps to address relay tripping issues during equipment startup or shutdown, including reviewing settings, analyzing event records, measuring inrush currents, and checking control logic. The protection relay tripping circuit refers to the critical electrical control loop that executes trip/close commands from protective relays to circuit breakers, ensuring rapid fault isolation in power systems. This system integrates protection logic with breaker control functions. Essential. Selectivity is a mandatory requirement for all protection, but the importance of it depends on the application. For example, unselective protection operation during a medium voltage network fault will cause an outage for an unnecessarily large number of consumers. Tripping relays are used to multiply the number of contacts available, provide isolation between the source and system operating element and meet the required duty.
